! CAUTION — CHOSEN AFTER LOOKING AT THE OUT-OF-SAMPLE

Luca chose this strategy on 07/10/2026 looking at the Valeris Alpha board with both out-of-sample periods visible (registry event 1584197), and its long-only version on 08/10/2026 (event 1590549): every out-of-sample number in this document is optimistic. It is not validated: OOS 1 t 1.75 against a gate of 1.96, OOS 2 t 2.25 against 3.92, and the anti data mining protocol did not admit it. The real test is the period from today on.

// STRATEGY RESEARCH NOTE · PAPER 848

ORB 5 MIN ON NQ

An opening-range breakout on the Nasdaq-100 future. The first 5-minute candle of the New York session picks the side, a Supertrend filter checks that the market is already running that way, and a very tight stop keeps the wrong days small. From Zarattini and Aziz (2023), rebuilt and optimised by Valeris Alpha.

// ABSTRACT

THE CASE.

Every regular session the **first 5-minute candle** on NQ (08:30-08:35 Chicago) picks the side. The trade is taken only if price is already at least 1.5 bar-ATRs beyond the **Supertrend** line on that side. Stop at **0.1 × the 14-day average daily range** (ADR), break-even after 0.5 ADR, exit at 15:00, up to three re-entries the same way. One trade in five wins; the winners are five times the losers.

On 1 NQ mini with the Valeris size: development (2017 to October 2022) **1,446 trades, $201,362, t 5.16**. OOS 1 (to December 2023) $45,027, t 1.75 against 1.96; OOS 2 (2024 to September 2026) $103,748, t 2.25 against 3.92. On 1 micro since 26/10/2022: **$14,519**, worst drawdown **$2,030** (30/06-17/09/2026).

Prop bootstrap (Matteo's method, fixed size, last 30% of days): evaluation within 30 days **17.4%** on LucidFlex 50K, 17.7% on 25K, **36.2%** on Apex 50K, far from the 60% target. Long only (Lato = 1): positive in all three periods, weaker on LucidFlex.

// READ THIS FIRST

Not validated. Chosen by looking at the out-of-sample, not admitted by the anti data mining protocol, and the best of three strategies from the same paper sent out of sample together. Trade it only as a forward test, on a rule fixed in advance.

01

// THE PAPER, IN FULL

HYPOTHESIS.

Zarattini, C., Aziz, A. (2023). *Can Day Trading Really Be Profitable? Evidence of Sustainable Long-term Profits from Opening Range Breakout (ORB) Day Trading Strategy vs. Benchmark in the US Stock Market.* SSRN working paper 4416622.

// WHAT THE AUTHORS TEST

The paper starts from a well-known fact: most people who day trade lose money. The authors ask whether a simple, fully mechanical rule can do better, and test the oldest intraday idea there is, the opening range breakout, on **QQQ** (the Nasdaq-100 ETF) with 5-minute bars from January 2016 to February 2023, a period that includes the 2020 crash and the 2022 bear market.

The rule. Look at the first 5-minute candle of the New York session (09:30-09:35). If it went up, buy at the start of the second candle; if it went down, sell short. The stop sits at the other end of the first candle (its low for a long, its high for a short). The target is ten times that risk (10R). Whatever is still open is closed at the end of the day. One trade a day at most, sized so that a stop costs 1% of the account, with leverage capped at four times (the US day-trading limit), commission included.

// WHY IT SHOULD WORK

The open concentrates information. Overnight news, earnings and the orders that piled up since the previous close all reach the market in the first minutes. The first candle is the market's first vote on that imbalance.

The imbalance persists. Large investors cannot fill big orders at once: they work them through the day. If the first minutes show buyers in control, the same flow tends to keep coming, and the day keeps moving the same way more often than chance would say. This is intraday momentum.

The payoff is asymmetric. A stop at the edge of the first candle is small; the 10R target, or the close, lets a trend day run. The rule can be wrong on most days and still make money, because a few trend days pay for many small losses. And it leaves nothing to judgement, which is where day traders usually fail.

// WHAT THEY FOUND · AS REPORTED BY THE AUTHORS, NOT REPRODUCED HERE

// ANNUAL ALPHA	// WITH TQQQ (3X)	// BUY AND HOLD	// TRADES
33%	**+1,484%**	**+169%**	**1 a day**
QQQ, net of commissions	total return, 2016-2023	QQQ over the same period	at most, every session

// HOW VALERIS ALPHA ADAPTED IT

NQ futures instead of QQQ, times in Chicago: the first candle is the 08:35 bar, measured from the close of the 08:30 bar (the last price before the open) to the close of the 08:35 bar. Entry at the close of the 08:35 bar, i.e. at the start of the second candle, as in the paper. The paper's candle-extreme stop and 10R target were left to the optimisation, which found its own exits, a filter and re-entries (section 07).

// THE RAW PAPER RULE ON NQ

Side from the first candle, entry at 08:35, exit at 15:00 (the cash close), no stop: on NQ in 2017-10/2022 it made **1,424 trades, $52,439** on 1 mini, 51% winners, **t 0.57**, worst drawdown $101,276. Positive, enough for step 1 of Alpha (average trade at least half the NQ threshold), but nowhere near significant on its own.

> *The paper gives the idea and the side; the optimisation gave everything else. What carries the result is the asymmetry the authors describe: one trade in five wins, and the winners are five times the losers.*

CONCLUSION OF §01

// THE RULE, STEP BY STEP

02 HOW IT WORKS.

Chicago (exchange) time, 5-minute bars stamped at their close: the 08:35 bar runs from 08:30 to 08:35. One position at a time, everything closed the same day. **ADR** = average high-low range of the last 14 regular sessions (08:35-15:00); **ATR** = average true range. Both are yesterday's values, fixed for the whole day.

1 · FIRST CANDLE	At 08:35, compare the close of the 08:35 bar with the close of the 08:30 bar. Up: the day is long. Down: the day is short. Unchanged: no trade today.
2 · FILTER	**Supertrend** with 10 bars and multiplier 2, on every 5-minute bar, night session included. Distance z = (close - Supertrend line) × side ÷ ATR(14) of the 5-minute bars. Trade only if **z ≥ 1.5**: price must already be running in the candle's direction, well clear of the line.
3 · ENTRY	Market order at the close of the 08:35 bar. Never on holidays or half-days; the first 14 regular sessions of the chart are skipped (ATR and ADR need them).
4 · STOP	**0.1 × ADR** from the entry price, active from the next bar. In 2026 that is 21 to 70 NQ points, median 39 (about $78 per micro). If a bar opens beyond the stop, the exit is at the open.
5 · BREAK-EVEN	When price has moved **0.5 ADR** in favour (using the highs or lows after the entry bar), from the next bar the stop moves to the entry price.
6 · TIME EXIT	A target at 5 ADR exists but was never touched in 2017-2026. Otherwise the base trade closes at the close of the **15:00** bar, the cash close.
7 · RE-ENTRIES	After any exit, wait 4 bars, then re-enter **the same side** at the close of the bar where the close crosses the level: for a long day, yesterday's close - 0.25 × daily ATR(14), crossed upwards; for a short day, yesterday's close + 0.25 ATR, crossed downwards. Same stop and break-even from the new price; re-entries close at **15:30** (never after 15:40). At most **4 trades a day**: the base and three re-entries.
8 · SIZE	Valeris sizes dynamically: weight = (median ADR of the last 250 sessions ÷ ADR)$^{0.5}$, between 0.25 and 4, so more contracts when the market is quiet. The prop numbers here use a **fixed size** (input TagliaDinamica = 0): same trades, constant contracts.

In MultiCharts the side can be restricted with the input **Lato**: 0 both sides (as optimised), 1 long only, -1 short only (section 06). The rule uses only open, high, low and close of NQ: no volume, no other market.

FIG. 1 STOP DISTANCE IN NQ POINTS, 0.1 × ADR, EVERY TRADING DAY 2017-2026

The stop follows volatility: median 4 points in 2017, 19 in 2020, 21 in 2023, 39 in 2026 (from 21 to 70). One NQ point is $2 on the micro and $20 on the mini. The worst single trade out of sample, −$162.55 on 1 micro (17/04/2025), came from an April 2025 ADR of about 810 points.

// ONE DAY, AND THE SHAPE OF THE EDGE

02 IN PRACTICE.

// AN EXAMPLE · 15/05/2025

08:35 the first candle is up and the filter passes: long at 21,332.50.
08:40 stopped out on the very next bar: -31 points.
09:45 after the pause, the close crosses back above the re-entry level (yesterday's close - 0.25 ATR): long again at 21,300.25.
15:30 time exit of the re-entry at 21,405.50: **+105.25 points**. One small loss, one trend day: the whole strategy in a single session.

// THE PROFILE, OUT OF SAMPLE

Since 26/10/2022: 1,008 trades on 693 of 1,011 sessions. **758 exit at the stop** (233 already at 08:40, the first bar), 43 at break-even, 207 at the time exit, none at the target. Only **19.6%** win, but winners average **+149 points** against -27 for losers. Median time in a trade: 15 minutes.

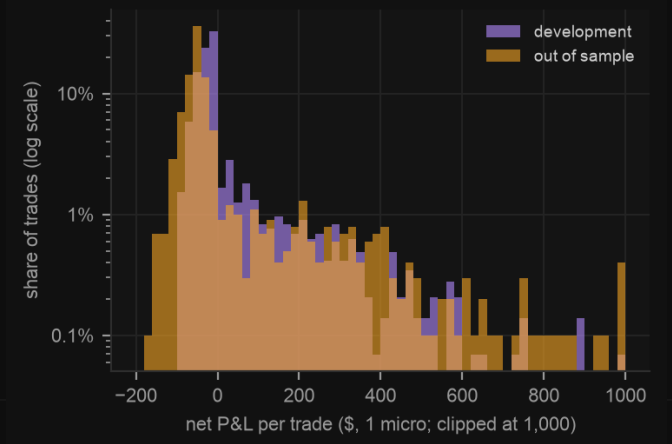

FIG. 2 TRADE RESULTS, 1 MICRO, LOG SCALE

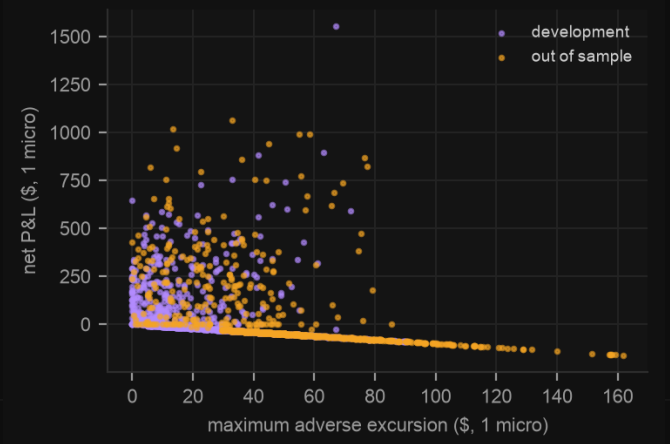

FIG. 3 ADVERSE EXCURSION VS RESULT, 1 MICRO

Fig. 2: a tall spike of small stop-outs and a long right tail (development: skew 3.5, kurtosis 17); development in purple, out of sample in amber. Fig. 3: the tight stop caps the adverse move (the diagonal of stop-outs); the big winners rarely went far against the position first.

> *A strategy of many small stops and a few long trend days. It does not need to be right often; it needs the trend days to keep coming, and the stops to be filled close to their level.*

CONCLUSION OF §02

// MULTICHARTS, EVERYTHING ON THE MICRO

03 CHART SETUP.

// DATA SERIES

SERIES	SYMBOL	BARS	ROLE
Data1	@MNQ	5 min	signal + orders
Data2	none	–	not used

// SESSION FIRST

Everything is in exchange time with the full CME session. With the "US Stocks" session MNQ becomes 09:30-16:00: the 08:35 bar and the night (needed by the Supertrend and the bar ATR) disappear, and the strategy trades something else **without any error**. History from 1 October 2021 (10/01/2021 in a US-format MultiCharts) so that the size weight has its 250 sessions.

// WHAT WAS CHECKED, WHAT IS STILL OPEN

03 CHECKS.

// THE LATO INPUT · 08/10/2026

Luca: "add an input to switch the shorts off". **Lato = 0** both sides, as Valeris; **Lato = 1** long only: a session whose first candle points down does **nothing**, no base trade and no re-entries; **Lato = -1** the mirror. One line in the base block; indicators, yesterday's values and size do not depend on it. Verified bar by bar since 2017: Lato 1 gives exactly the **1,267 long trades** of Valeris, Lato -1 exactly the 1,187 short ones, Lato 0 is unchanged. **Not yet recompiled in MultiCharts.**

// VERIFIED IN MULTICHARTS

On 08/10/2026 the verification copy of the signal (stop at the exact Valeris level, no LucidFlex close) on @NQ 5 minutes, history from 10 January 2022: in the common period 31/01/2022 - 23/09/2026, 1,200 trades in each, **1,199 identical** in entry time, side and exit time; the only different one is 02/02/2022, in the first weeks of the chart. **Since 26/10/2022: 1,008 of 1,008 identical.** Entry prices equal; exit prices within one tick, because MultiCharts fills the stop on a real tick (-110.6 points over 1,199 trades, about -0.09 per trade).

// INDEPENDENT EMULATOR

A bar-by-bar emulator that reads the raw price file and uses none of Valeris' signal code reproduces **2,454 of 2,454** trades since 2017: same session, time, side, entry and exit price. With the shipped inputs (stop rounded to the tick, LucidFlex close) the same entries and the same exit bars; only the 1,817 stop exits inside a bar fill 0.12 points worse on average. The signal text itself, run as it is, gives the same trades.

// LUCIDFLEX AND COSTS

No trade stays open past 15:45 or across 16:00: since 26/10/2022 entries 08:35-15:25, exits 08:40-15:30. OraChiusuraLucid 1545 changes no trade. No trades on half-days (list in the code, to 2027: to be extended every year). Valeris counts $9 per mini trade (commission + 1 tick); the prop bootstrap counts **$0.725 per micro** (Matteo's $2.25 + $5 per mini, ÷ 10). Put the real micro costs in the strategy properties.

2026 TO 23/09 · LONG ONLY ON 1 MICRO, FIXED

// FIXED OR DYNAMIC SIZE

The Valeris weight ranges from 0.47 to 1.31; on average 0.93 in development, 1.10 in OOS 1, 0.93 in OOS 2, and unrelated to the result of the trade (correlation −0.05 to 0.04). At a fixed mini: development t 5.03, OOS 1 1.73, OOS 2 2.03. The size adds little; the prop numbers use the fixed size.

// HOW TO READ IT

The average trade barely moves: $139 in development, $149 in OOS 1, $147 in OOS 2. What changes is the noise around it: profit factor from 1.67 to 1.34, worst drawdown twice as large in 2026. 2025 was the thin year.

Trades per session out of sample: one in 497 sessions, two in 109, three in 55, four in 32. Exit times: 233 at 08:40 and 103 at 08:45 (stops), 133 at 15:00 and 80 at 15:30 (almost all time exits).

> *All the profit comes from the time exits ($58,758 on 1 micro out of sample); the stops (−$44,208) are the price of finding the trend days. Out of sample the re-entries add almost nothing ($962 on 315 trades).*

CONCLUSION OF §04

// DEVELOPMENT, OOS 1, OOS 2

05 EQUITY / DD.

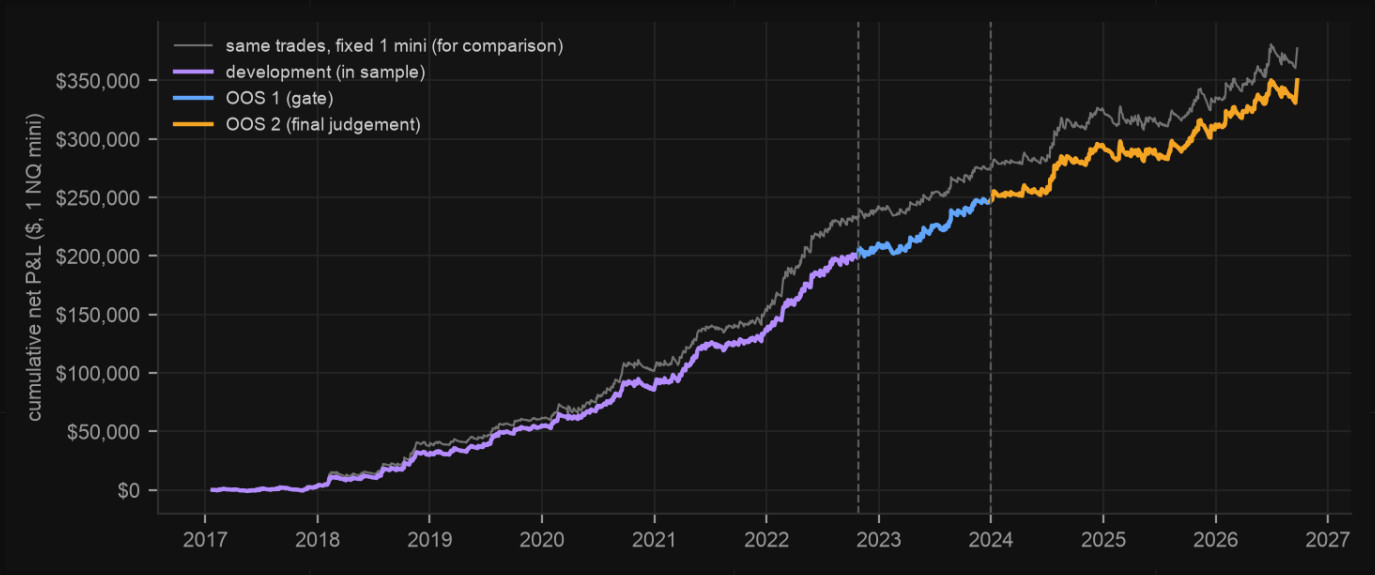

FIG. 1 EQUITY, 1 NQ MINI, VALERIS SIZE · PURPLE DEV · BLUE OOS 1 · AMBER OOS 2 · GREY FIXED

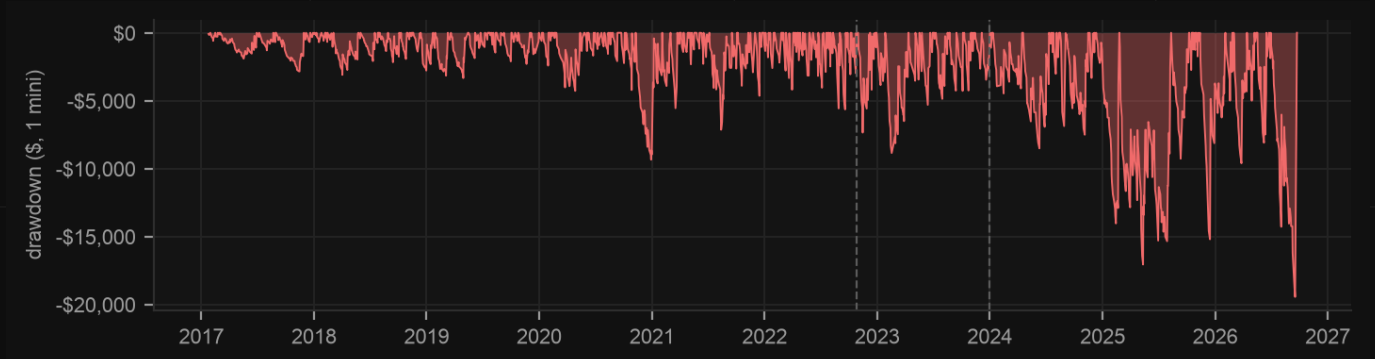

FIG. 2 DRAWDOWN FROM THE RUNNING PEAK, SAME EQUITY

// MAX DD · DEV.	// MAX DD · OOS 1	// MAX DD · OOS 2	// LOSING STREAK
−$9,343	**−$8,856**	**−$19,454**	**21 trades**
09/11/2020-29/12/2020	27/01/2023-17/02/2023	30/06/2026-17/09/2026	longest run of losers, 2017-2026

The deepest drawdown of nine years is the most recent one, and it is outside what the development predicted: the Monte Carlo of 2017-2022 put the worst drawdown between $6,175 and $13,255 (5th-95th percentile); the summer of 2026 went to $19,454 on the same mini. Part of it is the size of the market (ADR 389 points in 2026 against 145 on average in 2017-2022), part may be a change in the edge: the data cannot yet tell which.

// ON THE MICRO, THE TRADES THE PROP NUMBERS USE

05 OUT OF SAMPLE.

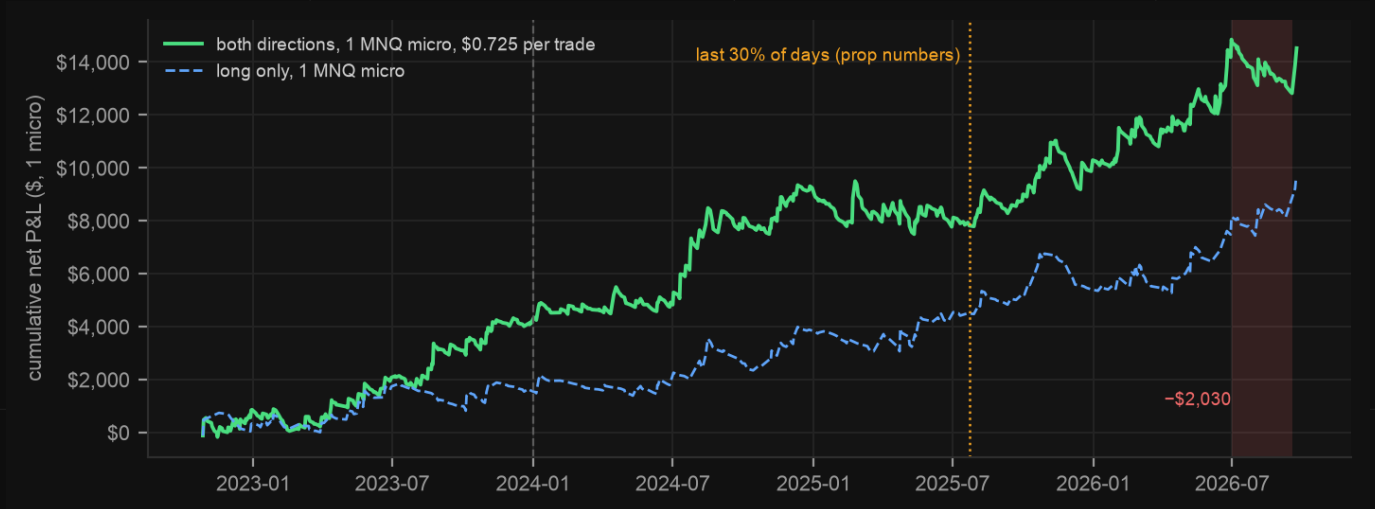

FIG. 1 OOS ON 1 MNQ, FIXED SIZE · DOTTED: LAST 30% OF DAYS · RED: THE 2026 DRAWDOWN

FIG. 2 MONTHLY NET ON 1 MICRO, YEAR TOTALS ON THE RIGHT

// POSITIVE MONTHS	// BEST MONTH	// WORST MONTH	// 2026 DRAWDOWN
81 / 117	**$2,318**	**−$1,534**	**−$2,030**
both sides, 1 micro, 2017-2026	June 2026, 1 micro	July 2026, 1 micro	30/06-17/09/2026

The best and the worst month of nine years are back to back, in the summer of 2026. The year still closes at $4,232 on 1 micro to 23/09, thanks to the last days (best session $1,064, 21/09/2026).

// LATO = 1, SAME STRATEGY WITHOUT THE SHORTS

06 LONG ONLY.

The long-only version is the same strategy in which sessions whose first candle points down do nothing, neither the base trade nor the re-entries. **Nothing is re-optimised.** Its trades are exactly the 1,267 long trades of the reference list (881 base trades and 386 re-entries), 509 of them since 26/10/2022. Luca asked for it on 08/10/2026 after seeing the strategy and its out-of-sample (registry event 1590549).

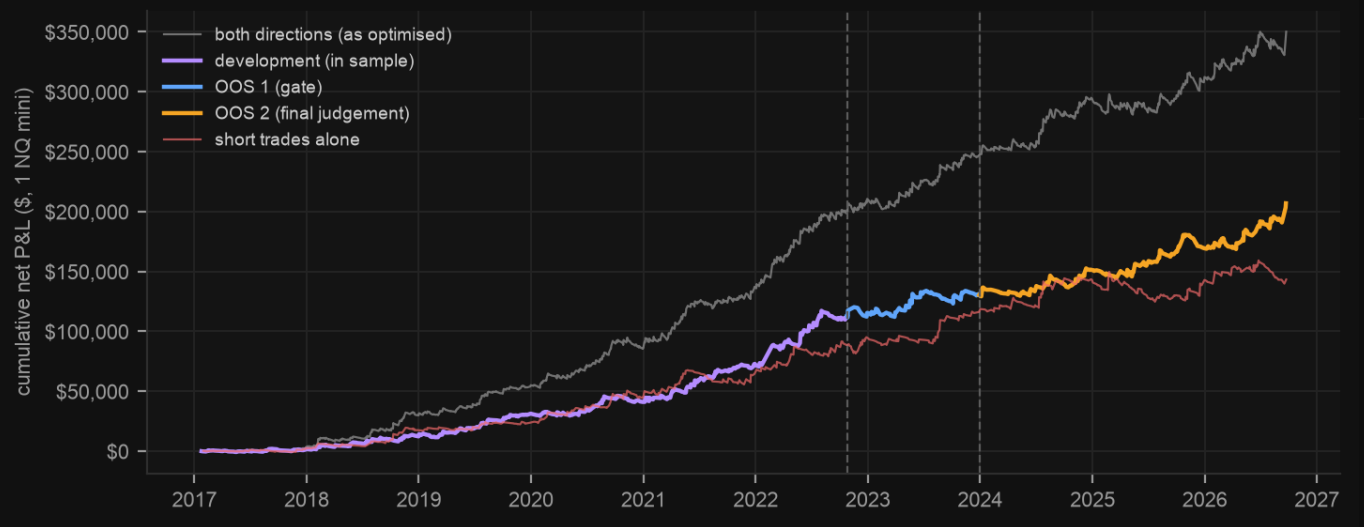

FIG. 1 LONG ONLY, 1 MINI, VALERIS SIZE · GREY: BOTH SIDES · RED: THE SHORTS ALONE

// HOW TO READ IT

Long and short both made money in development (t 4.13 and 3.17). Out of sample they took turns: in OOS 1 (late 2022-2023) the shorts carried the result ($27,566 against $17,461), in OOS 2 (2024-2026) the longs did ($76,592 against $27,156, t 2.38 against 0.82). The 2026 drawdown came from the shorts: from 30/06 to 17/09/2026 the long-only version closed at $2 on 1 micro while both sides lost $2,030.

// THE TWO SIDES, PERIOD BY PERIOD

06 LONG VS SHORT.

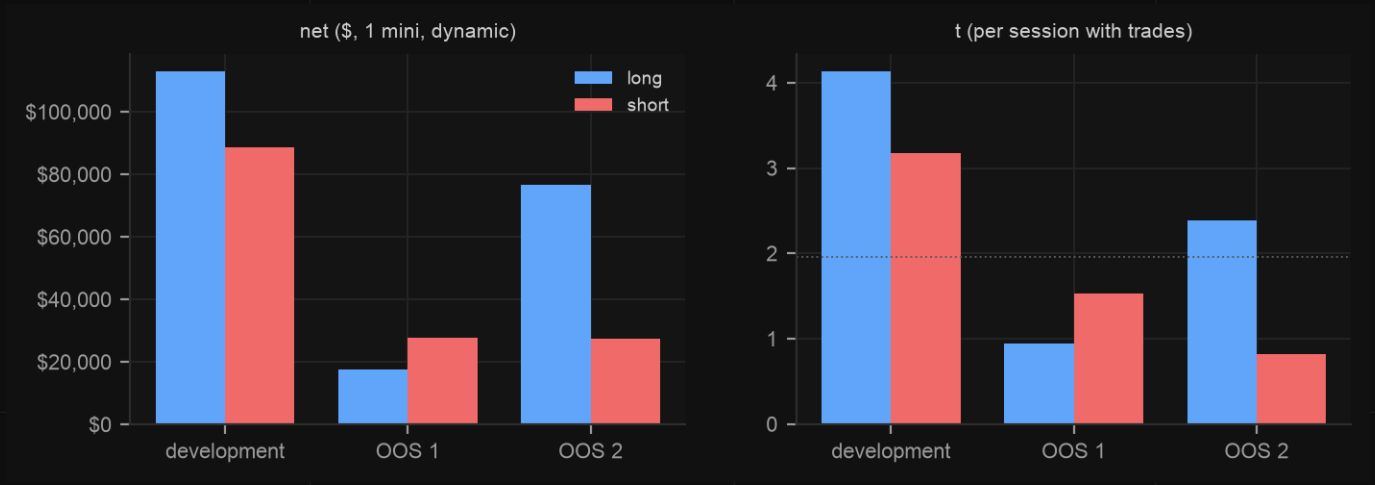

FIG. 1 LONG TRADES AGAINST SHORT TRADES, 1 MINI, DOTTED: T = 1.96

// WHY IT IS NOT THE BETTER VERSION

Chosen after the results. The idea of dropping the shorts came from looking at 2024-2026; its OOS numbers are a description, not a test (event 1590549).

NQ went up. From 2017 to 2026 the Nasdaq-100 rose many times over: on a rising market a long-only rule is favoured by the drift itself, with no skill needed. And the side that works changes: in OOS 1 (late 2022-2023, a strong rally) it was the shorts that carried the result.

Weaker where it matters. OOS 1 t 0.94, total out-of-sample net $9,538 against $14,519 on 1 micro, and half the trades. **The real test is from today on.**

// LONG ONLY ON THE PROP ACCOUNTS

Same bootstrap, same accounts (section 08): evaluation within 30 days **11.2%** on LucidFlex 50K (5 micro) against 17.4%, 11.1% on 25K, **40.2%** on Apex 50K (10 micro) against 36.2%. First payout within 60 days on LucidFlex 50K: 37.8% against 61.2%. Fewer trades means fewer chances in 30 days.

> *Long only is the same strategy seen from one side. It avoided the 2026 drawdown, but only because we know how 2026 went. If it is chosen, it must be chosen now, for the whole forward test, and not switched after a bad week.*

CONCLUSION OF §06

// HOW VALERIS ALPHA FOUND IT

07 ALPHA REPORT.

Valeris Alpha is the automatic research line of Valeris, run as a separate version: it reads a paper, tests the author's rule as it is, optimises the markets where the raw rule is positive, and opens the out-of-sample under rules fixed in advance, in the same anti data mining registry as Valeris. For paper 848 the raw rule was positive on NQ (step 1, a YES), so step 2 ran on two paths: a **recombination** of the paper's own parameters, and an exploratory **optimisation from the raw rule**. Each path has a **twin that must keep at least 800 trades at every step** (OP800). This strategy is the raw path, OP800 twin: **"848 NQ 5 grezzo OP800"** (grezzo = raw), run 11, batch 709c6201, optimised on 06/10/2026 on the development period only (02/01/2017-25/10/2022).

// THE OPTIMISATION CHAIN · T OF THE PLATEAU, DEVELOPMENT

STEP	CHOSEN	PLATEAU T	TRADES	CANDIDATES

5 · size	size by ADR (exponent 0.5, cap 4)	5.14 (5.16)	1,446	3 families, 2 admitted

PLATEAU T = MEDIAN T OF THE ZONE AROUND THE CHOICE · SIZE: ZONE (CENTRE)

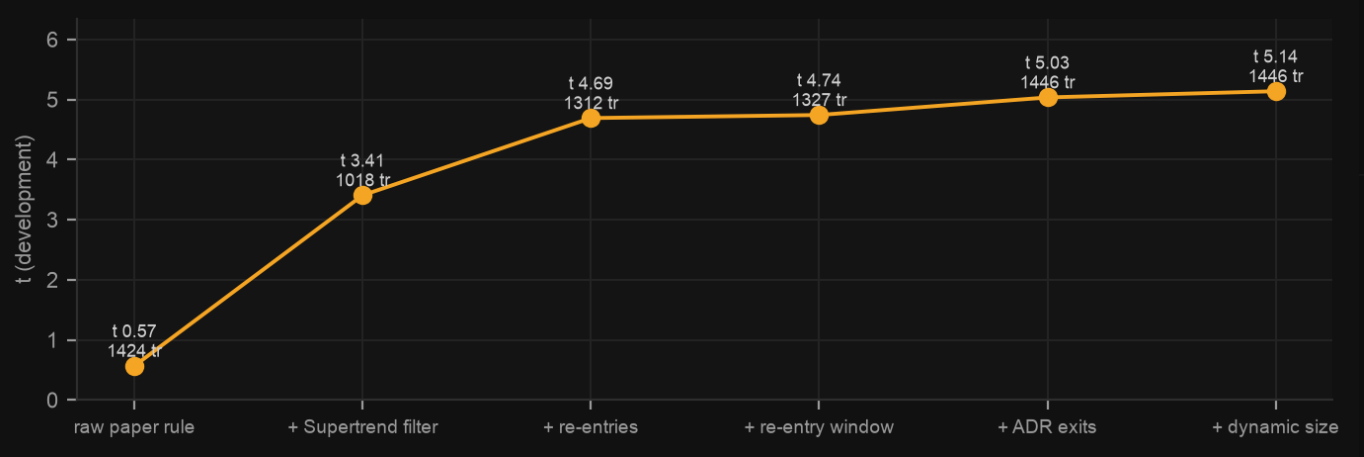

FIG. 1 HOW THE DEVELOPMENT T GREW ALONG THE CHAIN

Rule of the chain: a step is kept only if its plateau beats the previous step, with at least 800 trades, at least 88% of the neighbours positive, better in **both halves** of the development period, a smooth equity ($R^2 \geq 0.85$) and, at every step but the exits, a t above the 95th percentile of random subsets of the same trades (**chance**).

// EVERY CANDIDATE, AND EVERY TRIAL COUNTED

07 TRIALS.

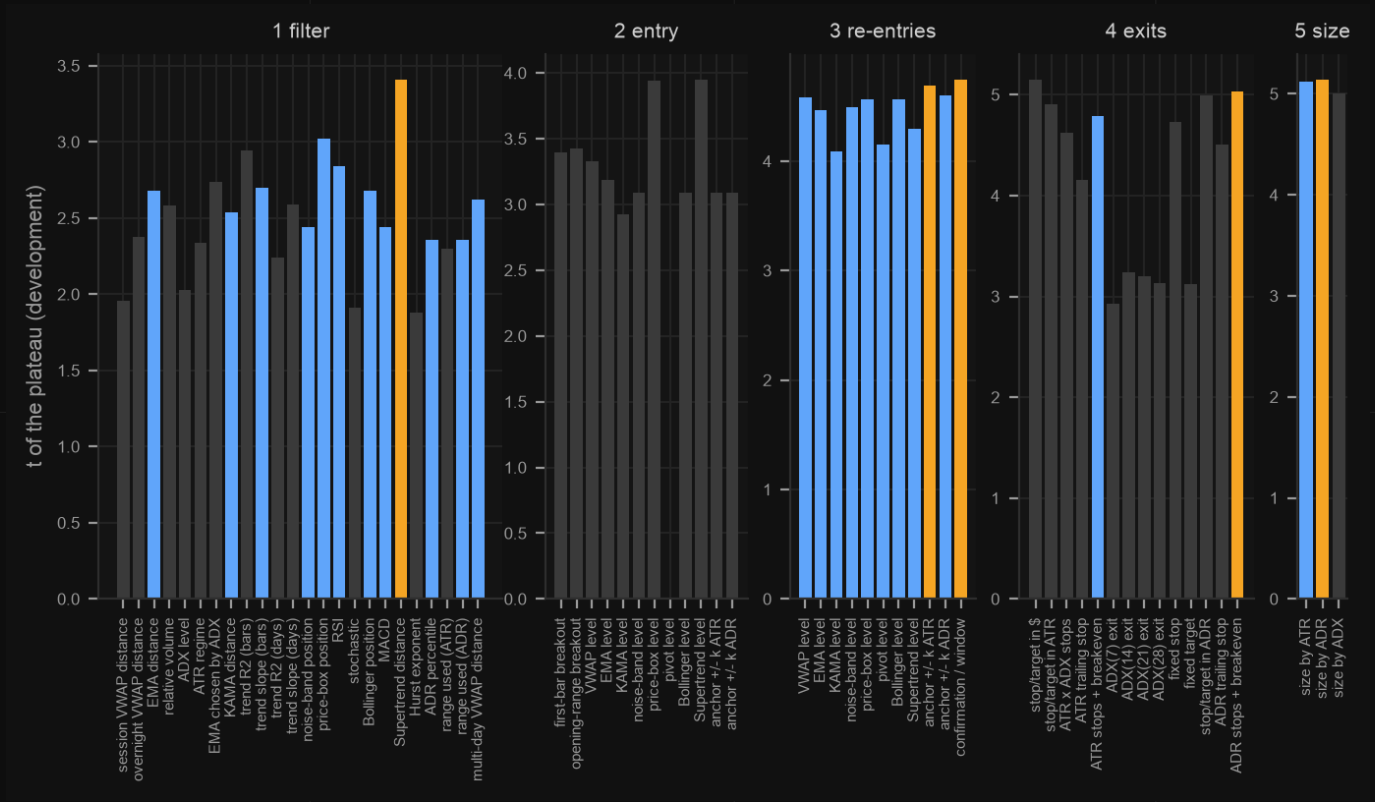

FIG. 1 EVERY FAMILY TRIED · AMBER CHOSEN · BLUE ADMITTED · DARK EXCLUDED

// TRIALS, FROM THE REGISTRY

RUNS ON PAPER 848	RUNS	TRIALS
first pass on the paper grid (5, 15, 30, 60 min)	4	4,805
raw paper rule (step 1)	1	1
recombination path, and its OP800 twin	2	4,858,611
raw path, and its OP800 twin (this strategy)	2	4,858,611
walk-forward re-selection, 6 windows	30	28,830
total on paper 848	39	9,750,858
all research in the registry, to date	—	1,390,974,822

// WHAT THE COUNT MEANS

This strategy's own run tried **2,429,305** combinations within the 20-million budget. The paper as a whole cost 9,750,858, and three of its optimisations were sent out of sample together. Each trial is booked in the registry before it runs. Picking the best of millions is exactly what the protocol corrects for, and why it says no (next page).

> *The chain made a significant development result out of a non-significant rule: from t 0.57 to t 5.16, with 2.4 million trials. That is the definition of a result that must be confirmed on data it has never seen.*

CONCLUSION OF THE CHAIN

// THE ANTI DATA MINING GATE, AND THE OUT-OF-SAMPLE

07 PROTOCOL.

// ANTI DATA MINING GATE · NOT ADMITTED

CRITERION	VALUE	LIMIT	
pre-registration (run booked before)	run 8837	–	pass
trial accounting	2,429,305	–	pass
sample (sessions)	1,502	≥ 252	pass
trades	1,446	≥ 100	pass
HAC test corrected for trials and reruns	p 0.0024	≤ 6.4e-10	fail
net with double costs	$189,267	> $0	pass
deflated Sharpe of the grid	not computed	≥ 0.95	fail
probability of backtest overfitting	not computed	≤ 0.2	fail
Reality Check on the whole grid	not computed	≤ 0.05	fail
walk-forward of the grid	not computed	≥ 0.6	fail
reconciled matrix	not computed	–	fail
base admitted by the protocol	no	–	fail
base on the same timeframe	yes	–	pass
base on the same period	2017-10/2022	–	pass

// WHY NOT ADMITTED

The daily net of the development is strongly positive by itself: Newey-West t 6.00, p 9.7 × 10^{-10}. Multiplied by the 2,429,306 trials of the run it becomes **0.0024**, against the 6.4 × 10^{-10} the registry allots to this run: one 5% error budget shared by every run ever booked (run 8,837: 0.05 ÷ (8,837 × 8,838)). The grid checks (deflated Sharpe, PBO, Reality Check, walk-forward) are not run inside the optimisation grids since 01/10/2026, and a check that was not run is not a pass. The raw base itself was not admitted. Hence: **exploratory out-of-sample only, no promotion.**

// DOUBLE OUT-OF-SAMPLE WITH GATE · 1 MINI, VALERIS SIZE

OUT OF SAMPLE	DATES	TRADES	NET	MEAN	T	THRESHOLD	PASS
OOS 1 · gate	26/10/2022-31/12/2023	302	$45,027	$149	1.75	1.96 fixed	no
OOS 2 · final	01/01/2024-23/09/2026	706	$103,748	$147	2.25	3.92 (573 uses)	no
ES, same rule, OOS 1		269	$27,829	$103	1.72	–	—
ES, same rule, OOS 2		607	−$12,855	−$21	−0.69	–	—

// PAPER 848: THREE FINALISTS SENT OUT OF SAMPLE TOGETHER

FINALIST	T DEV	T OOS 1	T OOS 2	NET OOS 1	NET OOS 2	LABEL
recombination	4.80	−0.49	1.59	−$9,177	$52,887	0 of 2
raw path	5.93	1.58	1.75	$17,543	$30,942	1 of 2
raw path, OP800 · this	5.16	1.75	2.25	$45,027	$103,748	1 of 2

// CANDIDATE STATUS: "1 OF 2"

Luca's rule for prop candidates (registry events 239245 and 239460): net positive in OOS 1 and in OOS 2 and an average trade above the NQ threshold ($70 per mini) in both, with no t required. This strategy has it: $149 and $147 per trade. "1 of 2" means the t was not taken in either period but the averages and the nets were good. It is the best of the three: choosing it among them is one more look at the out-of-sample.

at least 100 trades	1,446	pass
t ≥ 2, realistic fills	5.16	pass
positive with delay, costs × 2, +1 tick	$176,751	pass
best 5 trades below 80% of the profit	18%	pass
at least half the parameter variants hold	98%	pass
no one-step variant in loss	0/23	pass
Monte Carlo: P(loss) below 10%	0%	pass
positive on half the other markets	5/6	pass
anti data mining gate passed	no	fail

// MONTE CARLO AND SENSITIVITY

Monte Carlo of the development (2,000 block resamples, blocks of about 10 sessions): net $145,018 to $257,971 (5th-95th percentile), worst drawdown $6,175 to $13,255, P(loss) 0%.
Sensitivity: 23 one-step neighbours of the final parameters, none in loss; 98% of 44 variants hold. Only reversing the side (trading against the first candle) breaks it: t 0.51.
Tail: without the best 5% of trades the development is negative.

The level PROMISING means: it survives the main stresses, but the statistical checks of the protocol are not enough. It is a diagnostic and changes nothing in admission, gates or out-of-sample.

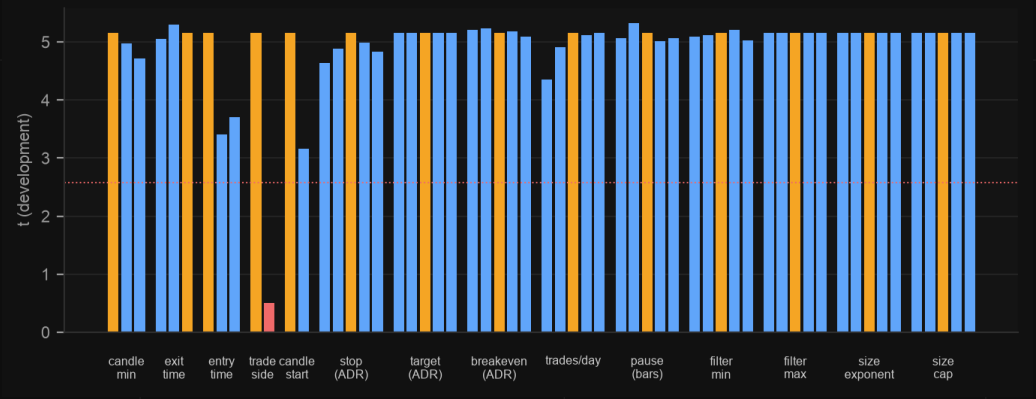

FIG. 1 ONE-STEP SENSITIVITY · AMBER CHOSEN · BLUE HOLDS · RED BREAKS

// REGIMES AND WALK-FORWARD

07 STABILITY.

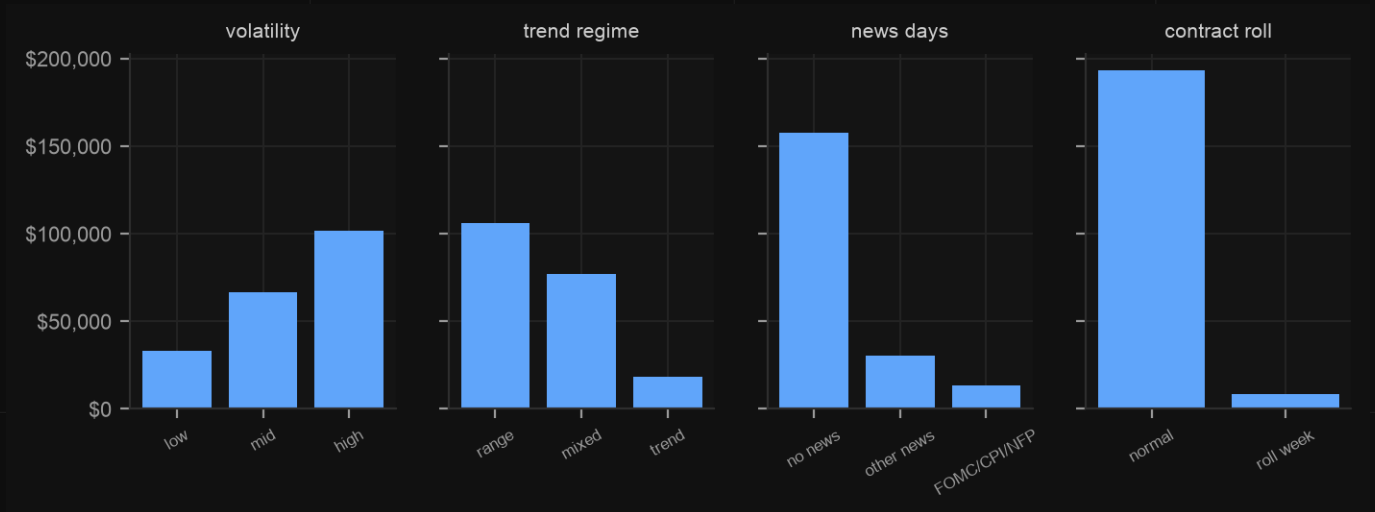

FIG. 1 DEVELOPMENT NET BY REGIME, 1 MINI, VALERIS SIZE

Positive in every regime. Strongest on **range and mixed days** (t 4.11 and 3.29) and in high volatility; weakest on strong-trend days (t 1.06), on FOMC, CPI and payroll days (t 1.07) and in **roll weeks** (t 0.53). 78% of the profit comes from days without major news. Every weekday is positive; Friday is the weakest.

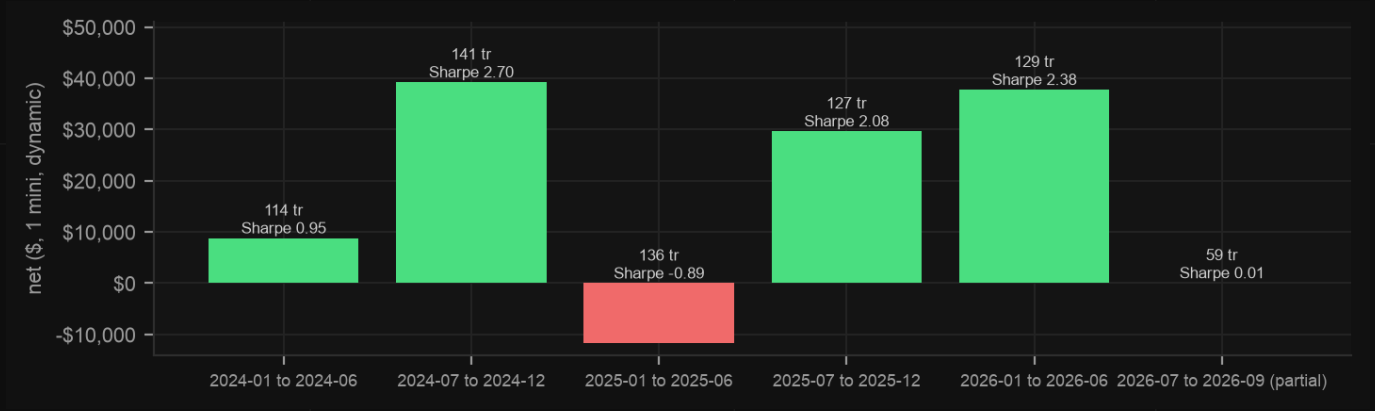

FIG. 2 FROZEN DEFINITION OVER OOS 2, HALF-YEAR BY HALF-YEAR, 1 MINI

Walk-forward at a fixed definition: 4 of 5 complete half-years of OOS 2 positive (the first half of 2025 lost −$11,765). **Rolling re-selection** (the whole chain re-run on 5-year windows, 6-month tests): no finalist in any window, so cash. The method that found this strategy would not have found it again, window by window.

Sensitivity (previous page): a neighbour holds when its net is above zero and its t is at least half the original. Target, filter maximum and size cap are inert: changing them changes nothing, because the target is never reached and the cap never binds.

// MATTEO'S METHOD, ON THE MICRO

08 EVALUATION.

The prop numbers follow **Matteo's bootstrap**, the rule for every prop calculation. The trades are the out-of-sample ones (1,008 trades from 27/10/2022) on 1 micro, $0.725 per micro per trade. The days are split by date: on the **first 70%** (27/10/2022-22/07/2025, 714 trading days) the method chooses the size, the smallest one statistically tied with the best; the numbers are reported on the **last 30%** (23/07/2025-23/09/2026, 306 days), which the choice never saw. For every purchase day, all sessions of the next 30 calendar days; days resampled with replacement, 20,000 simulations, checked with blocks of 5 and 10 days and on the real days in a row. Inside each day the trades run in order, each with its adverse excursion first, then its close.

// FIXED SIZE, DECLARED

In Valeris the 848 has a dynamic size, and the Alpha prop packs declared it "not computable". Here it runs at a **fixed number of micro** (input TagliaDinamica = 0): the same trades, the same adverse excursions, constant contracts. One position at a time.

// A STRONG FINAL 30%

The last 30% is the strategy's best stretch: $6,631 on 1 micro in 306 days, against $7,888 in the first 714: about **twice the daily rate**. The reported numbers are favourable; the first-70% column shows the other side.

// THE EXACT-RULES SIMULATOR · LAST 30% OF DAYS

A separate simulator with Lucid's rules as Luca gave them on 07/10 (events 1498353-54): consistency exactly 50%, promotion to a flat account in 30 minutes, max loss locked at $50,100, cost inside the excursion; the daily loss limits of $1,200 and $600 are still to be confirmed. **Cap**: when the day's closed profit reaches $1,500 the session closes; on the 50K this keeps the best day inside the 50% rule (the 25K uses the same $1,500 until a proportional cap is decided). With the bootstrap's own rules it reproduces the 17.4% exactly. One position at a time, so the two readings of the excursion coincide. Last 30%; the reference stays the bootstrap until Luca decides.

// FIRST PAYOUT WITHIN 30 AND 60 DAYS

09 FUNDED.

Luca's rule for the funded phase: the probability of reaching the **first payout within 30 and within 60 calendar days** of a funded account, each with its own size, chosen on the first 70% like the evaluation. These numbers **start from a funded account**: the evaluation is not included. Modelled rules: LucidFlex 50K, 5 qualifying days of $150, 50% consistency, max loss locking at +$100, minimum payout $500, size scaling 20-30-40 micro; Apex 50K, 5 qualifying days of $250, 50% consistency, a safety net of $2,100 before the first payout and an inactivity rule; LucidFlex 25K as the 50K, with $100 days and 10-20 micro.

E[PAYOUT] = EXPECTED FIRST PAYOUT PER FUNDED ACCOUNT, GROSS, LAST 30% · DAYS = MEDIAN TRADING DAYS
LF = LUCIDFLEX · BLOWN = MAX LOSS TOUCHED FIRST · THE REST ARE STILL RUNNING AT THE DEADLINE

> *Once funded, the first payout within 60 days comes 61% of the time on LucidFlex 50K at 2 micro, on the strong final 30% (51% on the first 70%). Within 30 days it is much less likely. The hard part is getting funded: one evaluation in six on LucidFlex 50K, one in three on Apex.*
>
> CONCLUSION OF §09

// THE LONG-ONLY VERSION, AND ONE ATTEMPT IN DOLLARS

09 VALUE.

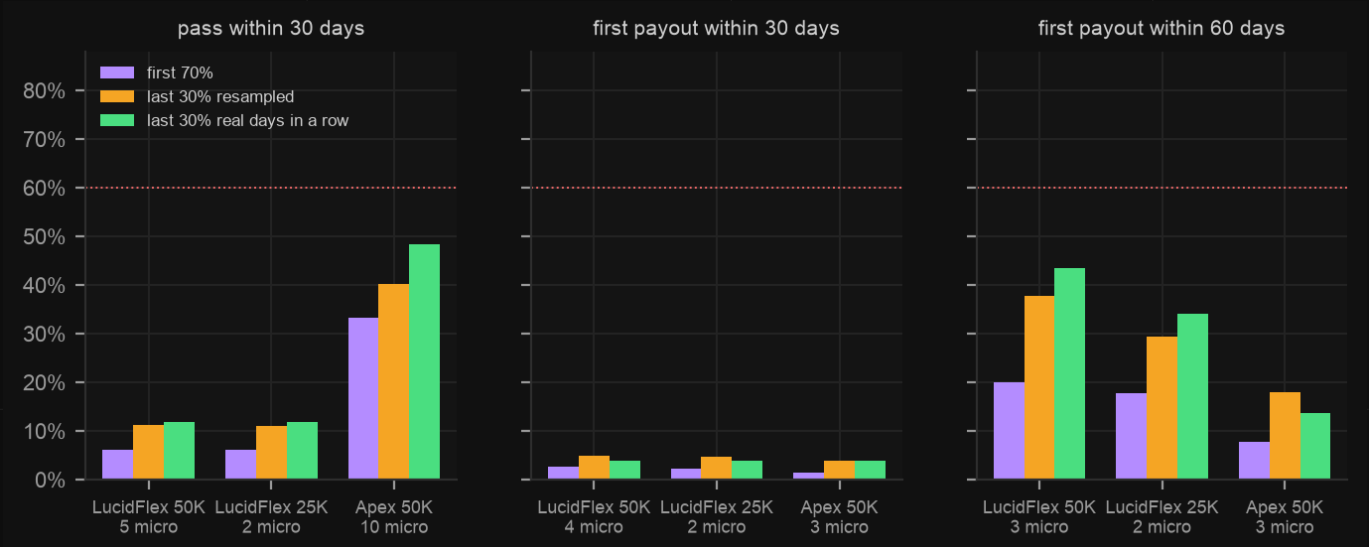

FIG. 1 LONG ONLY · FIRST 70%, LAST 30% RESAMPLED, LAST 30% IN A ROW

// VALUE OF ONE EVALUATION ATTEMPT · NOT PART OF THE METHOD

ACCOUNT	PRICE	PASS	COST PER PASS	EV 30 DAYS	EV 60 DAYS	LONG, 30 D	LONG, 60 D
LF 50K	$90.20	17.4%	$520	−$18	$23	−$81	−$26
LF 25K	$50.30	17.7%	$284	−$17	$9	−$46	−$23
Apex 50K	$100.00	36.2%	$416	−$74	$11	−$134	−$52

// HOW IT IS COMPUTED, AND WHAT IT LEAVES OUT

EV = P(pass within 30 days, last 30%) × (trader share × expected first payout of a funded account − activation fee) − evaluation price. Cost per pass = price ÷ pass rate, plus the $140 activation fee on Apex. Only the first payout counts; later payouts, resets and discounts are ignored, and the trader share is 90% on LucidFlex. It is a sketch of the order of magnitude, with the favourable final 30%: around zero for the two-sided strategy, negative for the long-only version.

> *On these accounts the strategy alone is roughly a break-even bet per attempt, and only on the strongest stretch of data. Its value, if any, is as one more independent leg of a pack.*

CONCLUSION OF §09

// THE 2026 DRAWDOWN, THE TIGHT STOP, THE ROLL

10 WEAK POINT.

// 2026 DRAWDOWN	// AS SHIPPED	// JULY 2026	// LF 50K MAX LOSS
−$2,030	**−$2,041**	**−$1,534**	**$2,000**
1 micro, 30/06-17/09/2026	same period, stop on the tick	the worst month since 2017	LucidFlex 50K, trailing

One drawdown, one account. From 30 June to 17 September 2026 the strategy alone lost about $2,000 on a single micro, about 1,000 NQ points: as much as the maximum loss of a LucidFlex 50K. It is not an error in the MultiCharts version: it is the strategy itself. Alone on a LucidFlex 50K, even at 1 micro, that stretch would have blown the account. On 1 mini with the Valeris size the same stretch is −$19,454. The shorts did it: the long side closed the period flat.

The stop is very tight. 0.1 ADR is 21-70 points in 2026; three trades in four end at the stop, 233 of 1,008 on the first bar. Entry and time exits are market orders at the bar close. Live, every tick of slippage weighs much more than on a strategy with wide stops: one extra tick on entry and exit costs $1.00 per micro per trade, about $1,008 over the 1,008 out-of-sample trades, 7% of their net.

// THE ROLL

Valeris' NQ data are not adjusted. At the roll the price jumps by about 1% at 17:00, and the jump enters the Supertrend, the bar ATR, ATR and ADR and yesterday's close. @MNQ must be **unadjusted and roll on the same evening as @NQ** (since 2025 the Monday evening of the expiry week: +308 points on 15/06/2026, +294.75 on 14/09/2026). With the roll one session late or early, 20 to 25 of the 1,008 out-of-sample trades change (-358 to -677 points). Check it once on the chart.

// MICRO AGAINST MINI

MultiCharts computes the signal on MNQ prices, Valeris on NQ: they can differ by a tick. Out of sample, 5 first candles were one tick wide, 2 filters within 0.05 of the threshold, 14 re-entry bars within a tick of the level. In a pessimistic test (a random tick on 30% of the prices) 1,005-1,007 of 1,008 entries stay the same.

// THE STOP BETWEEN TWO TICKS

0.1 ADR is a number with decimals. The shipped signal rounds the distance up to whole ticks: same exit bars, fills on a real tick: 7,532.50 points out of sample instead of 7,624.96.

> *The edge survives the stress test (+1 tick each side: t 4.81; +2 ticks: 4.46), but the account is not: one ordinary drawdown of this strategy is a whole LucidFlex 50K. It can only live inside a pack, or at a size that survives it.*

> CONCLUSION OF §10

// WHAT THIS DOCUMENT DOES NOT SHOW

11 VERDICT.

// ANALYSES

ANALYSIS	STATUS
OOS 1 (gate)	t 1.75 < 1.96
OOS 2 (final)	t 2.25 < 3.92
Anti data mining	not admitted
No look-ahead	ok, 3,240 checks
Two engines, physical cut	ok
Robustness level	promising
Walk-forward, fixed	4/5 half-years
Walk-forward, re-selection	no finalist
MultiCharts, verification copy	1,008 / 1,008
Account version with Lato	not compiled
Forward or live trading	none

// 01, CHOSEN AFTER SEEING THE OOS

Picked from the Alpha board with both out-of-sample periods visible (event 1584197), the long only too (1590549), and the best of the three 848 finalists. Its out-of-sample numbers are optimistic by construction.

// 02, MILLIONS OF TRIALS

2,429,305 in its run, 9,750,858 on the paper. Corrected for them, the significance is gone.

// 03, BELOW BOTH THRESHOLDS

OOS 1 t 1.75, OOS 2 t 2.25. Only the development clears its bar.

// 04, FAVOURABLE PROP NUMBERS

Reported on a strong final 30%, at a fixed size that Valeris did not optimise.

// 05, ONE MARKET, A THIN TAIL

ES with the same rule: t −0.69 in OOS 2. Without the best 5% of trades the development is negative.

NOT VALIDATED / FORWARD TEST ONLY

A simple ORB on NQ that stayed positive in both out-of-sample periods with the same average trade as in development, but below both thresholds, chosen after looking, and with a recent drawdown as large as a LucidFlex 50K account. On the prop accounts it passes an evaluation **17%** of the time on LucidFlex 50K and **36%** on Apex 50K: far from 60%.

// FORWARD TEST

A proposal for Luca to fix and register **before the first trade**: the account signal as it is, side chosen now (Lato 0 or 1), 1 micro fixed or simulation. After 120 trades (about six months with both sides, about a year long only) go on only if the net is positive and the average trade is at least $5 per micro, a third of the out-of-sample. Stop at once if the drawdown passes $2,500 per micro. Log every fill against the signal's price. No change of parameters on the way.

// WHAT NOT TO DO

Do not run it alone on a LucidFlex 50K: its 2026 drawdown is the whole account. Do not size up to pass an evaluation faster. Do not switch Lato after a bad week. Do not use the dynamic size on a prop account.

// WHERE TO START

Compile the account signal with Lato in MultiCharts and compare its List of Trades with the emulator. Check the roll on @MNQ. Then the pack: the 848 added to Luca's seven strategies, recomputed with the same bootstrap.

Not financial advice. Simulated results on historical data, hypothetical and with hindsight; they are not real trades. Costs and slippage are estimated. Prop rules are modelled, not guaranteed, and change. Past results do not indicate future ones.
